

Learn Python in Y minutes

Source: [learnpython](#)

1. Primitive Datatypes and Operators
2. Variables and Collections
3. Control Flow
4. Functions
5. Classes
6. Modules
7. Advanced

Single line comments start with a # symbol.

```
""" Multiline strings can be written  
    using three "s, and are often used  
    as comments  
    """
```

1. Primitive Datatypes and Operators

You have numbers

3 # => 3

Math is what you would expect

1 + 1 # => 2

8 - 1 # => 7

10 * 2 # => 20

35 / 5 # => 7

Division is a bit tricky. It is integer division and floors the results automatically.

`5 / 2 # => 2`

To fix division we need to learn about floats.

```
2.0 # This is a float
```

```
11.0 / 4.0 # => 2.75 ahhh...much better
```

Result of integer division truncated down both for positive and negative.

```
5 // 3 # => 1
```

```
5.0 // 3.0 # => 1.0 # works on floats too
```

```
-5 // 3 # => -2
```

```
-5.0 // 3.0 # => -2.0
```

Note that we can also `import division` module

to carry out normal division with just one /

```
from __future__ import division
```

```
11 / 4 # => 2.75 ...normal division
```

```
11 // 4 # => 2 ...floored division
```

Modulo operation

`7 % 3 # => 1`

Exponentiation (x to the yth power)

```
2 ** 4 # => 16
```

Enforce precedence with parentheses

`(1 + 3) * 2 # => 8`

Boolean Operators: Note “and” and “or” are case-sensitive

```
True and False  # => False  
False or True   # => True
```

Note using Bool operators with ints

```
0 and 2 # => 0
-5 or 0 # => -5
0 == False # => True
2 == True # => False
1 == True # => True
```

negate with not

```
not True    # => False
```

```
not False   # => True
```

Equality is ==

```
1 == 1  # => True  
2 == 1  # => False
```

Inequality is `!=`

```
1 != 1  # => False  
2 != 1  # => True
```

More comparisons

```
1 < 10  # => True
1 > 10  # => False
2 <= 2  # => True
2 >= 2  # => True
```

Comparisons can be chained!

```
1 < 2 < 3  # => True  
2 < 3 < 2  # => False
```

Strings are created with " or '

"This is a string."

'This is also a string.'

Strings can be added too!

```
"Hello " + "world!"  # => "Hello world!"
```

Strings can be added without using '+'

```
"Hello " "world!" # => "Hello world!"
```

... or multiplied

```
"Hello" * 3 # => "HelloHelloHello"
```

A string can be treated like a list of characters

```
"This is a string"[0]  # => 'T'
```

You can find the length of a string

```
len("This is a string")  # => 16
```

String formatting with %

Even though the % string operator will be deprecated on Python 3.1 and removed

later at some time, it may still be good to know how it works.

```
x = 'apple'
y = 'lemon'
z = "The items in the basket are %s and %s" % (x, y)

# z => 'The items in the basket are apple and lemon'
```

A newer way to format strings is the format method.

This method **is** the preferred way

```
"{} is a {}".format("This", "placeholder")
```

```
"{0} can be {1}".format("strings", "formatted")
```

You can use keywords **if** you don't want to count.

```
"{name} wants to eat {food}".format(name="Bob", food="lasagna")
```

None is an object

```
None # => None
```

Don't use the equality “==” symbol to compare objects to None

Use “is” instead

```
"etc" is None # => False
```

```
None is None # => True
```

The 'is' operator tests for object identity.

This isn't very useful when dealing with primitive values, but is very useful when dealing with objects.

- Any object can be used in a Boolean context.

The 'is' operator tests for object identity.

This isn't very useful when dealing with primitive values, but is very useful when dealing with objects.

- Any object can be used in a Boolean context.
- The following values are considered `False`:

The 'is' operator tests for object identity.

This isn't very useful when dealing with primitive values, but is very useful when dealing with objects.

- Any object can be used in a Boolean context.
- The following values are considered `False`:
 - `None`

The 'is' operator tests for object identity.

This isn't very useful when dealing with primitive values, but is very useful when dealing with objects.

- Any object can be used in a Boolean context.
- The following values are considered `False`:
 - `None`
 - zero of any numeric type (e.g., `0`, `0L`, `0.0`, `0j`)

The 'is' operator tests for object identity.

This isn't very useful when dealing with primitive values, but is very useful when dealing with objects.

- Any object can be used in a Boolean context.
- The following values are considered `False`:
 - `None`
 - zero of any numeric type (e.g., `0`, `0L`, `0.0`, `0j`)
 - empty sequences (e.g., `''`, `()`, `[]`)

The 'is' operator tests for object identity.

This isn't very useful when dealing with primitive values, but is very useful when dealing with objects.

- Any object can be used in a Boolean context.
- The following values are considered `False`:
 - `None`
 - zero of any numeric type (e.g., `0`, `0L`, `0.0`, `0j`)
 - empty sequences (e.g., `''`, `()`, `[]`)
 - empty containers (e.g., `{}`, `set()`)

The 'is' operator tests for object identity.

This isn't very useful when dealing with primitive values, but is very useful when dealing with objects.

- Any object can be used in a Boolean context.
- The following values are considered False:
 - None
 - zero of any numeric type (e.g., 0, 0L, 0.0, 0j)
 - empty sequences (e.g., '', (), [])
 - empty containers (e.g., {}, set())
 - instances of user-defined classes meeting certain conditions see:
<https://docs.python.org/2/reference/datamodel.html#object.nonzero>

All other values are truthy (using the `bool()` function on them returns `True`).

```
bool(0)    # => False  
bool("")   # => False
```

2. Variables and Collections

Python has a print statement

```
print "I'm Python. Nice to meet you!"  
# => I'm Python. Nice to meet you!
```

Simple way to get input data from console

```
input_string_var = raw_input(  
    "Enter some data: ")  # Returns the data as a string
```

```
input_var = input("Enter some data: ")  # Evaluates the data  
## Warning: Caution is recommended for input() method usage
```

Note: In python 3, input() is deprecated and raw_input() is renamed to input()

No need to declare variables before assigning to them.

```
some_var = 5
```

```
# Convention is to use lower_case_with_underscores
```

```
some_var # => 5
```

Accessing a previously unassigned variable is an exception.

See [Control Flow](#) to learn more about exception handling.

```
some_other_var    # Raises a name error
```

- if can be used as an expression

Accessing a previously unassigned variable is an exception.

See [Control Flow](#) to learn more about exception handling.

```
some_other_var    # Raises a name error
```

- if can be used as an expression
- Equivalent of C's '?:' ternary operator

```
"yahoo!" if 3 > 2 else 2    # => "yahoo!"
```

Lists store sequences

```
li = []
```

#You can start with a prefilled list

```
other_li = [4, 5, 6]
```

Add stuff to the end of a list with append

```
li.append(1)    # li is now [1]
li.append(2)    # li is now [1, 2]
li.append(4)    # li is now [1, 2, 4]
li.append(3)    # li is now [1, 2, 4, 3]

# Remove from the end with pop
li.pop()        # => 3 and li is now [1, 2, 4]

# Let's put it back
li.append(3)    # li is now [1, 2, 4, 3] again.
```

Access a list like you would any array

```
li[0]    # => 1
```

```
# Assign new values to indexes that have already  
# been initialized with =
```

```
li[0] = 42
```

```
li[0]    # => 42
```

```
li[0] = 1  # Note: setting it back to the original value  
# Look at the last element
```

```
li[-1]    # => 3
```

Looking out of bounds is an IndexError

```
li[4] # Raises an IndexError
```

You can look at ranges with slice syntax.

It's a closed/open range for you mathy types.

```
li[1:3]  # => [2, 4]
# Omit the beginning
li[2:]   # => [4, 3]
# Omit the end
li[:3]   # => [1, 2, 4]
# Select every second entry
li[::2]  # => [1, 4]
# Reverse a copy of the list
li[::-1] # => [3, 4, 2, 1]
# Use any combination of these to make advanced slices
# li[start:end:step]
```

Remove arbitrary elements from a list with “del”

```
del li[2]  # li is now [1, 2, 3]
```

You can add lists

```
li + other_li  # => [1, 2, 3, 4, 5, 6]  
## Note: values for li and for other_li are not modified.
```

Concatenate lists with “extend()”

```
li.extend(other_li)  # Now li is [1, 2, 3, 4, 5, 6]
```

Remove first occurrence of a value

```
li.remove(2)    # li is now [1, 3, 4, 5, 6]  
li.remove(2)    # Raises a ValueError as 2 is not in the list
```

Insert an element at a specific index

```
li.insert(1, 2)  # li is now [1, 2, 3, 4, 5, 6] again
```

Get the index of the first item found

```
li.index(2)    # => 1  
li.index(7)    # Raises a ValueError as 7 is not in the list
```

Check for existence in a list with “in”

```
1 in li # => True
```

Examine the length with “len()”

```
len(li)  # => 6
```

Tuples are like lists but are immutable.

```
tup = (1, 2, 3)
tup[0] # => 1
tup[0] = 3 # Raises a TypeError
```

You can do all those list thingies on tuples too

```
len(tup)    # => 3
tup + (4, 5, 6)  # => (1, 2, 3, 4, 5, 6)
tup[:2]       # => (1, 2)
2 in tup      # => True
```

You can unpack tuples (or lists) into variables

```
a, b, c = (1, 2, 3)  # a is now 1, b is now 2 and c is now 3  
d, e, f = 4, 5, 6   # you can leave out the parentheses
```

Tuples are created by default if you leave out the parentheses

```
g = 4, 5, 6 # => (4, 5, 6)
```

Now look how easy it is to swap two values

```
e, d = d, e  # d is now 5 and e is now 4
```

Dictionaries store mappings

```
empty_dict = {}
```

```
## Here is a prefilled dictionary
```

```
filled_dict = {"one": 1, "two": 2, "three": 3}
```

Look up values with []

```
filled_dict["one"] # => 1
```

Get all keys as a list with “keys()”

```
filled_dict.keys() # => ["three", "two", "one"]
```

Note - Dictionary key ordering is not guaranteed.

Your results might not match this exactly.

Get all values as a list with “values()”

```
filled_dict.values()  # => [3, 2, 1]
```

Note - Same as above regarding key ordering.

Get all key-value pairs as a list of tuples with “items()”

```
filled_dict.items()
```

```
# => [("one", 1), ("two", 2), ("three", 3)]
```

Check for existence of keys in a dictionary with “in”

```
"one" in filled_dict  # => True  
1 in filled_dict      # => False
```

Looking up a non-existing key is a `KeyError`

```
filled_dict["four"] # KeyError
```

Use “get()” method to avoid the KeyError

```
filled_dict.get("one")    # => 1  
filled_dict.get("four")   # => None
```

The get method supports a default argument when the value is not found

```
filled_dict.get("one", 4)  # => 1  
filled_dict.get("four", 4) # => 4
```

*## note that filled_dict.get("four") is still => None
(get doesn't set the value in the dictionary)*

set the value of a key with a syntax similar to lists

```
filled_dict["four"] = 4
```

```
# now, filled_dict["four"] => 4
```

“setdefault()” inserts into a dictionary only if the given key isn't present

```
filled_dict.setdefault("five", 5)  
# filled_dict["five"] is set to 5
```

```
filled_dict.setdefault("five", 6)  
# filled_dict["five"] is still 5
```

Sets store ... well sets (which are like lists but can contain no duplicates)

```
empty_set = set()
```

```
## Initialize a "set()" with a bunch of values
```

```
some_set = set([1, 2, 2, 3, 4])
```

```
# some_set is now set([1, 2, 3, 4])
```

```
## order is not guaranteed,
```

```
## even though it may sometimes look sorted
```

```
another_set = set([4, 3, 2, 2, 1])
```

```
# another_set is now set([1, 2, 3, 4])
```

Since Python 2.7, `{}` can be used to declare a set

```
filled_set = {1, 2, 2, 3, 4}  # => {1, 2, 3, 4}
```

```
## Add more items to a set
```

```
filled_set.add(5)
```

```
# filled_set is now {1, 2, 3, 4, 5}
```

Do set intersection with &

```
other_set = {3, 4, 5, 6}  
filled_set & other_set  # => {3, 4, 5}
```

Do set union with |

```
filled_set | other_set  # => {1, 2, 3, 4, 5, 6}
```

Do set difference with -

`{1, 2, 3, 4} - {2, 3, 5} # => {1, 4}`

Do set symmetric difference with ^

`{1, 2, 3, 4} ^ {2, 3, 5} # => {1, 4, 5}`

Check if set on the left is a superset of set on the right

```
{1, 2} >= {1, 2, 3} # => False
```

Check if set on the left is a subset of set on the right

```
{1, 2} <= {1, 2, 3} # => True
```

Check for existence in a set with in

```
2 in filled_set    # => True  
10 in filled_set   # => False
```

3. Control Flow

Let's just make a variable

```
some_var = 5
```

if statement. Indentation is significant in python!

```
## prints "some_var is smaller than 10"
if some_var > 10:
    print "some_var is totally bigger than 10."
elif some_var < 10: # This elif clause is optional.
    print "some_var is smaller than 10."
else: # This is optional too.
    print "some_var is indeed 10."
```

For loops iterate over lists

```
for animal in ["dog", "cat", "mouse"]:  
    # You can use {0} to interpolate formatted strings.  
    # (See above.)  
    print "{0} is a mammal".format(animal)  
  
# prints:  
#     dog is a mammal  
#     cat is a mammal  
#     mouse is a mammal
```

“range(number)” returns a list of numbers

from zero to the given number

```
"""  
prints:  
    0  
    1  
    2  
    3  
"""  
for i in range(4):  
    print i
```

“range(lower, upper)” returns a list of numbers

from the lower number to the upper number

```
"""  
prints:  
    4  
    5  
    6  
    7  
"""  
for i in range(4, 8):  
    print i
```

While loops go until a condition is no longer met.

```
"""
prints:
    0
    1
    2
    3
"""
x = 0
while x < 4:
    print x
    x += 1  # Shorthand for x = x + 1
```

Handle exceptions with a try/except block

Works on Python 2.6 and up:

```
try:
    # Use "raise" to raise an error
    raise IndexError("This is an index error")
except IndexError as e:
    pass # Pass is just a no-op.
    # Usually you would do recovery here.
except (TypeError, NameError):
    pass # Multiple exceptions can be handled together,
    # if required.
else: # Optional clause to the try/except block. Must follow all except clauses.
    print "All good!"
    # Runs only if the code in try raises no exceptions
finally: # Execute under all circumstances
    print "We can clean up resources here"
```

Instead of try/finally to cleanup resources you can use a with statement

```
with open("myfile.txt") as f:  
    for line in f:  
        print line
```

4. Functions

Use “def” to create new functions

```
def add(x, y):  
    print "x is {0} and y is {1}".format(x, y)  
    return x + y  # Return values with a return statement
```

Calling functions with parameters

```
add(5, 6)
```

```
# => prints out "x is 5 and y is 6" and returns 11
```

Another way to call functions is with keyword arguments

Keyword arguments can arrive in any order.

```
add(y=6, x=5)
```

Functions with a variable number of positional args will be interpreted as a tuple by using *

```
def varargs(*args):  
    return args
```

```
varargs(1, 2, 3) # => (1, 2, 3)
```

Functions may take a variable number of keyword args,

they will be interpreted as a dict by using `**`

```
def keyword_args(**kwargs):  
    return kwargs
```

```
## Let's call it to see what happens  
keyword_args(big="foot", loch="ness")  
# => {"big": "foot", "loch": "ness"}
```

You can do both at once, if you like

```
def all_the_args(*args, **kwargs):  
    print args  
    print kwargs  
  
    """  
    all_the_args(1, 2, a=3, b=4) prints:  
        (1, 2)  
        {"a": 3, "b": 4}  
    """
```

When calling functions, you can do the opposite of args/kwargs!

Use `*` to expand positional args and use `**` to expand keyword args

```
args = (1, 2, 3, 4)
```

```
kwargs = {"a": 3, "b": 4}
```

```
all_the_args(*args)
```

```
# equivalent to foo(1, 2, 3, 4)
```

```
all_the_args(**kwargs)
```

```
# equivalent to foo(a=3, b=4)
```

```
all_the_args(*args, **kwargs)
```

```
# equivalent to foo(1, 2, 3, 4, a=3, b=4)
```

you can pass args and kwargs along to other functions that take args/kwargs

by expanding them with * and ** respectively

```
def pass_all_the_args(*args, **kwargs):  
    all_the_args(*args, **kwargs)  
    print varargs(*args)  
    print keyword_args(**kwargs)
```

Function Scope

```
x = 5
```

```
def set_x(num):  
    # Local var x not the same as global variable x  
    x = num    # => 43  
    print x    # => 43
```

```
def set_global_x(num):  
    global x  
    print x    # => 5  
    x = num    # global var x is now set to 6  
    print x    # => 6
```

```
set_x(43)  
set_global_x(6)
```

Python has first class functions

```
def create_adder(x):  
    def adder(y):  
        return x + y  
  
    return adder  
  
add_10 = create_adder(10)  
add_10(3)  # => 13
```

There are also anonymous functions

```
(lambda x: x > 2)(3)  # => True
```

```
(lambda x, y: x ** 2 + y ** 2)(2, 1)  # => 5
```

There are built-in higher order functions

```
map(add_10, [1, 2, 3]) # => [11, 12, 13]
```

```
map(max, [1, 2, 3], [4, 2, 1]) # => [4, 2, 3]
```

```
filter(lambda x: x > 5, [3, 4, 5, 6, 7]) # => [6, 7]
```

We can use list comprehensions for nice maps and filters

```
[add_10(i) for i in [1, 2, 3]] # => [11, 12, 13]  
[x for x in [3, 4, 5, 6, 7] if x > 5] # => [6, 7]
```

You can construct set and dict comprehensions as well.

```
{x for x in 'abcddeef' if x in 'abc'}  
# => {'a', 'b', 'c'}
```

```
{x: x ** 2 for x in range(5)}  
# => {0: 0, 1: 1, 2: 4, 3: 9, 4: 16}
```

5. Classes

We subclass from object to get a class (1/3)

```
class Human(object):
```

```
    # A class attribute. It is shared by all instances of this class  
    species = "H. sapiens"
```

```
    # Basic initializer, this is called when this class is instantiated.  
    # Note that the double leading and trailing underscores denote objects  
    # or attributes that are used by python but that live in user-controlled  
    # namespaces. You should not invent such names on your own.
```

```
def __init__(self, name):
```

```
    # Assign the argument to the instance's name attribute  
    self.name = name
```

```
    # Initialize property  
    self.age = 0
```

Continue (2/3)

```
# An instance method. All methods take "self" as the first argument
def say(self, msg):
    return "{0}: {1}".format(self.name, msg)

# A class method is shared among all instances
# They are called with the calling class as the first argument
@classmethod
def get_species(cls):
    return cls.species

# A static method is called without a class or instance reference
@staticmethod
def grunt():
    return "*grunt*"

```

Continue (3/3)

```
# A property is just like a getter.  
# It turns the method age() into an read-only attribute  
# of the same name.  
@property  
def age(self):  
    return self._age  
  
# This allows the property to be set  
@age.setter  
def age(self, age):  
    self._age = age  
  
# This allows the property to be deleted  
@age.deleter  
def age(self):  
    del self._age
```

Instantiate a class

```
i = Human(name="Ian")  
print i.say("hi")  
# prints out "Ian: hi"  
  
j = Human("Joel")  
print j.say("hello")  
# prints out "Joel: hello"
```

Call our class method

```
i.get_species() # => "H. sapiens"
```

Change the shared attribute

```
Human.species = "H. neanderthalensis"  
i.get_species()  # => "H. neanderthalensis"  
j.get_species()  # => "H. neanderthalensis"
```

Call the static method

```
Human.grunt() # => "*grunt*"
```

Update the property

```
i.age = 42
```

Get the property

```
i.age # => 42
```

Delete the property

```
del i.age  
i.age  # => raises an AttributeError
```

6. Modules

You can import modules

```
import math  
  
print math.sqrt(16)  # => 4
```

You can get specific functions from a module

```
from math import ceil, floor
```

```
print ceil(3.7)    # => 4.0
```

```
print floor(3.7)   # => 3.0
```

You can import all functions from a module.

```
## Warning: this is not recommended  
from math import *
```

You can shorten module names

```
import math as m
```

```
math.sqrt(16) == m.sqrt(16)  # => True
```

```
## you can also test that the functions are equivalent  
from math import sqrt
```

```
math.sqrt == m.sqrt == sqrt  # => True
```

Python modules are just ordinary python files.

*## You can write your own, and import them. The name of the
module is the same as the name of the file.*

*## You can find out which functions and attributes
defines a module.*

```
import math
```

```
dir(math)
```

*## If you have a Python script named math.py in the same
folder as your current script, the file math.py will
be loaded instead of the built-in Python module.
This happens because the local folder has priority
over Python's built-in libraries.*

7. Advanced

Generators (1/4)

```
## A generator "generates" values as they are requested instead of storing  
## everything up front
```

```
## The following method (*NOT* a generator) will double all values and  
## store it in `double_arr`. For large size of iterables, might get huge!
```

```
def double_numbers(iterable):  
    double_arr = []  
    for i in iterable:  
        double_arr.append(i + i)  
    return double_arr
```

```
## Running the following would mean we'll double all values first and  
## return all of them back to be checked by our condition
```

```
for value in double_numbers(range(1000000)): # `test_non_generator`  
    print value  
    if value > 5:  
        break
```

Generators (2/4)

```
## We could instead use a generator to "generate" the doubled value  
## as the item is being requested
```

```
def double_numbers_generator(iterable):  
    for i in iterable:  
        yield i + i
```

```
## Running the same code as before, but with a generator, now allows us  
## to iterate over the values and doubling them one by one as they are  
## being consumed by our logic. Hence as soon as we see a value > 5, we  
## break out of the loop and don't need to double most of the values  
## sent in
```

```
## MUCH FASTER!
```

```
for value in double_numbers_generator(xrange(1000000)): # `test_generator`  
    print value  
    if value > 5:  
        break
```

Generators (3/4)

```
## BTW: did you notice the use of `range` in `test_non_generator`  
## and `xrange` in `test_generator`?
```

```
## Just as `double_numbers_generator` is the generator version of  
## `double_numbers` We have `xrange` as the generator version of `range`  
## `range` would return back and array with 1000000 values for us to use  
## `xrange` would generate 1000000 values for us as we request / iterate  
## over those items
```

```
## Just as you can create a list comprehension, you can create generator  
## comprehensions as well.
```

```
values = (-x for x in [1, 2, 3, 4, 5])  
for x in values:  
    print(x)  # prints -1 -2 -3 -4 -5 to console/terminal
```

Generators (4/4)

You can also cast a generator comprehension directly to a list.

```
values = (-x for x in [1, 2, 3, 4, 5])  
gen_to_list = list(values)  
  
print(gen_to_list)  # => [-1, -2, -3, -4, -5]
```

Decorators (1/4)

*## A decorator is a higher order function, which accepts and returns
a function.*

*## Simple usage example - add_apples decorator will add 'Apple' element
into fruits list returned by get_fruits target function.*

```
def add_apples(func):  
    def get_fruits():  
        fruits = func()  
        fruits.append('Apple')  
        return fruits  
    return get_fruits
```

Decorators (2/4)

```
@add_apples
def get_fruits():
    return ['Banana', 'Mango', 'Orange']

## Prints out the list of fruits with 'Apple' element in it:
## Banana, Mango, Orange, Apple
print ', '.join(get_fruits())
```

Decorators (3/4)

```
## in this example beg wraps say  
## Beg will call say. If say_please is True  
## then it will change the returned message
```

```
from functools import wraps
```

```
def beg(target_function):  
    @wraps(target_function)  
    def wrapper(*args, **kwargs):  
        msg, say_please = target_function(*args, **kwargs)  
        if say_please:  
            return "{} {}".format(msg, "Please! I am poor :(")  
        return msg  
  
    return wrapper
```

Decorators (4/4)

```
@beg
```

```
def say(say_please=False):  
    msg = "Can you buy me a beer?"  
    return msg, say_please
```

```
print say()  
# Can you buy me a beer?
```

```
print say(say_please=True)  
# Can you buy me a beer? Please! I am poor :(
```
